

# Dissemination of IT for the Promotion of Materials Science (DoITPoMS)

- What is it?
- How did it come about?
- How can it be used?
- What have we learnt?

# Department of Materials Science & Metallurgy

- Supported by the **Fund for the Development of Teaching and Learning (FDTL)**.

## 5 Partner Institutions:

- University of Leeds, **Department of Materials**
- University of Manchester / UMIST, **Manchester Materials Science Centre**
- London Metropolitan University (formerly University of North London), **School of Polymer Technology**
- Oxford Brookes University, **School of Engineering**
- University of Sheffield, **Department of Engineering Materials**
  
- Close links with the **UK Centre for Materials Education** and with the **MATTER** project, both based at the University of Liverpool.

### Aims, objectives and resources

To build on recognised expertise in the use of information technology (IT) in enhancing the student learning experience and to disseminate these techniques within the Materials Education community in the UK.

#### *Objectives*

- To create a primary archive of photomicrographs, digital video clips, etc, for use by teachers in developing secondary resources, and as a teaching and learning resource in its own right.
- To create a library of exemplar teaching and learning packages (TLPs) covering common topics and making use of video clips and other material from the primary archive.

#### *Resources*

To date the following resources have been created and are undergoing continuing development:

- [Micrograph Library](#)
- [Library of Teaching and Learning Packages](#)

A library of video clips is currently under development.

Further information

This alloy is typical of many copper based alloy systems. The dendrite structure shows coring (variation in solute concentration). The light areas are rich in nickel and the darker areas are low in nickel. Chill casting extracts heat quickly enough to prevent significant solid state diffusion, resulting in cored dendrites. The centres of the dendrites that cool near the liquidus temperature, are nickel rich compared to the outer layers that solidify at progressively lower temperatures. Because the partition coefficient is positive the outer layers solidify with progressively lower nickel concentrations. The observed pattern results from the intersection of the plane of polish and the randomly orientated regions of equal solute concentration.

## Library of Teaching and Learning Packages for Materials Science

The following teaching and learning packages (TLPs) are largely based on first year materials science laboratory work in the Department of Materials Science and Metallurgy at the University of Cambridge, with the exception of "The Jominy End Quench Test". This is largely based on content developed at Manchester, with additional contributions from Oxford Brookes, Cambridge and MATTER.

- Atomic Scale Structure of Materials
- Beam Stiffness
- Introduction to Dislocations
- Introduction to Mechanical Testing
- Slip in Single Crystals
- Fracture of Glass
- The Ductile-Brittle Transition
- Optical Microscopy and Specimen Preparation
- Phase Diagrams and Solidification
- Diffraction and Imaging
- X-ray Diffraction
- Introduction to Photoelasticity
- The Jominy End Quench Test
- The Stiffness of Rubber
- Solid Solutions
- The Glass Transition in Polymers
- Thermal Expansion and the Bi-material Strip

## Library of Teaching and Learning Packages for Materials Science

### THE STIFFNESS OF RUBBER

This teaching and learning package is based on a two experiments which demonstrate the behaviour of rubber under tension. The first displays the unusual behaviour of a rubber strip when heated under tension; the second considers the behaviour of a rubber membrane under tension. In both cases the behaviour is considered theoretically in terms of the molecular structure of rubber and the thermodynamic entropy changes involved.

### Theory of rubber conformation

#### Polymer Coils

Polymer molecules are made up of many smaller units called monomers. A rubber is a fully amorphous, lightly cross-linked polymer, above  $T_g$ . They are normally composed of a -C-C- backbone chain. The bond angle is fixed at  $109.5^\circ$ , but the torsion angle can change, allowing the macroscopic shape of the chain to vary from being linear to being highly coiled and convoluted.

In this diagram, on the left each blue line represents a C-C link. The arrow shows the end-to-end distance of the chain segment, depicted as a thickened line. The segments tend to coil up to some extent, rather than aligning in a straight line. This can be thought of as the system increasing its entropy. The probability distribution for the end-to-end distance can be

## Contraction experiment

The theory predicts that the stiffness of rubber is proportional to the temperature.

$$\sigma = \frac{KTN}{V_0} \left( \lambda_3 - \frac{1}{\lambda_3^2} \right)$$

The result of this is that, if the rubber is extended under a fixed load, it is likely to contract when it is heated (even after allowance is made for the thermal expansion).

This can be observed using the following apparatus:

### Questions

#### Quick questions

*You should be able to answer these questions without too much difficulty after studying this TLP. If not then you should go through it again!*

1. Materials expand when heated because:
  - a The mean interatomic distance increases as the thermal energy of the atoms increases
  - b The heat takes up extra volume forcing the material to expand
  - c The rubber melts
  - d There are more chemical bonds being formed

2. When rubber is put under uniaxial tension it:
  - a Contracts
  - b Extends
  - c Explodes
  - d Rises

3. Rubber differs from all other materials in that:

# Use of Resources

- Lecturers / teachers:
  - learn from it
  - get ideas for practicals or demonstrations
  - use *instead* of practicals / demonstrations
  - use resources for lecture notes / visuals
  - set as homework
- Students:
  - support for courses (e.g. to access at home)
  - prepare for a lab. class
  - project work
  - revision / general broadening of knowledge

**Micrographs as illustrations**, for overheads, lecture hand-outs, question sheets, etc.

## **1.1. The drive to equilibrium.**

1.1.1 Quenching can lead to a supersaturated solid solution which will, on annealing, tend towards its equilibrium phase distribution; beginning with precipitation.

1.1.2 The metastable martensitic microstructure, which may show a lenticular morphology (due to shearing during the transformation), will revert to .....

## 2.1. Preferential precipitation on grain boundaries

The  $\theta$  precipitates preferentially form on Al grain boundaries, as these are excellent heterogeneous nucleation sites.

The depletion of Cu near the boundaries to these precipitates is one reason for the formation of adjacent **precipitation free zones (PFZ)**.

-from “Further information”

Grain boundaries act as sinks for solute and vacancies. This has the effect of increasing the precipitation on the grain boundary relative to the surrounding region, often leaving a precipitate free zone (PFZ) close to the boundary. This phenomenon is detrimental to the material since there is a reduction in precipitation hardening in the PFZ.

-from Glossary

..... the glossary for key words:

## Dendrite

When metallic phases form during solidification, they often do so along certain preferred directions that relate to their crystal structure. The resultant tree-like structures are called dendrites.

# From the Teaching & Learning Packages:

## A Dislocation in a 2D Close Packed Plane

QuickTime™ and a  
Sorenson Video 3 decompressor  
are needed to see this picture.

# Use of Resources

- Lecturers / teachers:
  - learn from it
  - get ideas for practicals or demonstrations
  - use *instead* of practicals / demonstrations
  - use resources for lecture notes / visuals
  - set as homework
- Students:
  - support for courses (e.g. to access at home)
  - prepare for a lab. class
  - project work
  - revision / general broadening of knowledge

# What did we learn?

- Importance of format and style
- Critical mass for resource library
- More risky nature of TLPs
- Principal input from partner institutions was for trials and dissemination

## Advantages of:

- Advertising course content
- On-line feedback

# Get students involved!

- They enjoy it (empowerment!)
- They learn from it
- They get enthused about materials science
- They have great ideas (are often closer to the market)
